Preliminary

Definition 1.1 (d-regular Graph) A graph G = (V, E) is d-regular if every vertex in V has degree d.

Definition 1.2 (Set) [n] is the shorthand for the set $\{i: 1 \le i \le n\}$

Definition 1.3 (Multilinear Polynomial)

Polynomial Commitments

In this chapter, We present an general polynomial commitments scheme for arbitrary dimension t. The scheme is an extension of the polynomial commitments scheme for t=2 described in [1]. We first extend the scheme to the t=3 situation so that readers can have a good intuition on how it works. Then we generalize it to arbitrary t with detailed analysis available.

2.1 Notation

Let g be a multilinear polynomial with n coefficients. For simplicity we assume that $n=m^t$ for some integer m. And let u denote the coefficient vector of g in the Lagrange basis, which means u represents all evaluations of g over inputs in hypercube $\{0,1\}^{\log n}$. We can rearrange u to be a $\underbrace{n^{\frac{1}{t}} \times n^{\frac{1}{t}} \times \cdots \times n^{\frac{1}{t}}}_{t \text{ times}}$ matrix, such that we can index entries in this matrix easily by elements from set $[m]^t$.

Let $N=\rho^{-1}\cdot m$ and Enc: $\mathbb{F}^m\to\mathbb{F}^N$ represent the encoding function of a linear code with a constant rate $\rho>0$ and a constant minimum relative distance $\gamma>0$.

Let $\operatorname{Enc}_i(M)$ denote the function that encode every stripes in the ith dimension of matrix M using encoding function Enc. For example, $\operatorname{Enc}_1(M)$ will encode each column of a $n \times n$ matrix and produce a $N \times m$ matrix.

Lemma 2.1 (Polynomial Evaluation [1]) For an l-variate multilinear polynomial g represented in the Lagrange basis via a vector $u \in \mathbb{F}^n$ where $2^l = n$, given an evaluation point $x \in \mathbb{F}^l$, g(x) can be evaluated using the following tensor product identity:

$$g(x) = \langle (x_1, 1 - x_1) \otimes (x_2, 1 - x_2) \otimes \cdots \otimes (x_l, 1 - x_l), u \rangle$$

And for any $1 \le t \le l$, there always exist vectors $q_1, q_2, \dots, q_t \in \mathbb{F}^{n^{\frac{1}{t}}}$ such that the following holds:

$$(x_1, 1-x_1) \otimes (x_2, 1-x_2) \otimes \cdots \otimes (x_l, 1-x_l) = q_1 \otimes q_2 \otimes \cdots \otimes q_t$$

2.2 Polynomial Commitments for t = 3

Commitment Phase.

Let $M_0 = u$ and $M_0' = \operatorname{Enc}_1(\operatorname{Enc}_2(M_0)) \in \mathbb{F}^{N \times N \times m}$. Send M_0' to the verifier.

Testing Phase.

The testing phase consists of 2 rounds, with each round reducing the dimension by 1.

In round 1, the verifier will send a random value $r_1 \in \mathbb{F}^m$ to the prover. The prover will compute a linear combination $M_1 \in \mathbb{F}^{m \times m}$ across the 3rd dimension of matrix M_0 . Namely, $M_1[i,j] = \sum_{k=1}^m r_1[k] \cdot M_0[i,j,k]$ for $1 \le i,j \le m$. Let $M_1' = \operatorname{Enc}_1(M_1) \in \mathbb{F}^{N \times m}$. Then the prover sends M_1' to the verifier.

In round 2, the verifier will send a random value $r_2 \in \mathbb{F}^m$ to the prover. The prover will compute a linear combination $M_2 \in \mathbb{F}^m$ across the 2nd dimension of matrix M_1 . Namely, $M_2[i] = \sum_{k=1}^m r_2[k] \cdot M_1[i,k]$. Let $M_2' = M_2 \in \mathbb{F}^m$. Then the prover sends M_2' to the verifier.

Then the verifier will perform a probabilistic checking to make sure M'_0 , M'_1 and M'_2 are consistent with each other. Formally speaking, the verifier will sample l random tuple (i_1, i_2, i_3) from space $[N] \times [N] \times [N]$. For each tuple (i_1, i_2, i_3) , let $M'_1[i_1, *]$ denotes the i_1 -th row in M'_1 . The verifier will check whether the following equation holds:

$$\operatorname{Enc}(M'_1[i_1,*])[i_2] = \sum_{k=1}^m r_1[k] \cdot M'_0[i_1,i_2,k]$$

$$\operatorname{Enc}(M'_2[*])[i_1] = \sum_{k=1}^m r_2[k] \cdot M'_1[i_1,k]$$

Evaluation Phase.

Let $q_1, q_2, q_3 \in \mathbb{F}^m$ be vectors such that $g(x) = \langle q_1 \otimes q_2 \otimes q_3, u \rangle$. The evaluation phase is identical to the testing phase, except that in round i, the random value r_i is replaced by q_i . If all consistent checks passed, then the verifier outputs $\langle M'_2, q_3 \rangle$ as g(x).

2.3 Polynomial Commitments for Arbitrary t

2.3.1 Protocol

Commitment Phase.

Let
$$M_0 = u$$
 and $M_0' = \operatorname{Enc}_1 \circ \operatorname{Enc}_2 \circ \cdots \circ \operatorname{Enc}_{t-1}(M_0) \in \mathbb{F}$ $\underbrace{N \times N \times \cdots \times N}_{t-1 \text{ times}} \times m$. Send M_0' to the verifier.

Testing Phase.

The testing phase consists of t-1 rounds, with each round reducing the number of dimensions by 1.

In round i, the verifier will send a random value $r_i \in \mathbb{F}^m$ to the prover. The prover will compute a linear combination $M_i \in \mathbb{F}$ t-i times across

the last dimension of matrix M_{i-1} . Namely, for $1 \le j_1, j_2, \cdots, j_{t-i} \le m$:

$$M_i[j_1, j_2, \cdots, j_{t-i}] = \sum_{k=1}^m r_i[k] \cdot M_{i-1}[j_1, j_2, \cdots, j_{t-i}, k]$$

Let

$$M'_i = \operatorname{Enc}_1 \circ \operatorname{Enc}_2 \circ \cdots \circ \operatorname{Enc}_{t-i-1}(M_i) \in \mathbb{F} \underbrace{N \times N \times \cdots \times N}_{t-i-1 \text{ times}} \times m$$

Then the prover sends M'_i to the verifier.

Then the verifier will perform a probabilistic checking to make sure M'_0 , M'_1 , M'_2, \cdots, M'_{t-1} are consistent with each other. Formally speaking, the verifier M'_2, \dots, M'_{t-1} are consistent with each other. The will sample l random tuple (i_1, i_2, \dots, i_t) from space $[N] \times [N] \times \dots \times [N]$.

For each tuple (i_1, i_2, \dots, i_t) , the verifier will check whether the following equation holds for every $i \in [t-1]$:

$$\operatorname{Enc}(M'_{i}[i_{1}, i_{2}, \cdots, i_{t-i-1}, *])[i_{t-i}] = \sum_{k=1}^{m} r_{i}[k] \cdot M'_{i-1}[i_{1}, i_{2}, \cdots, i_{t-i}, k]$$

Evaluation Phase.

Let $q_1, q_2, \dots, q_t \in \mathbb{F}^m$ be vectors such that $g(x) = \langle q_1 \otimes q_2 \otimes \dots \otimes q_t, u \rangle$. The evaluation phase is identical to the testing phase, except that in round i, the random value r_i is replaced by q_i . If all consistent checks passed, then the verifier outputs $\langle M'_{t-1}, q_t \rangle$ as g(x).

2.4 Implementation Details

2.4.1 Merkle Tree Commitment

Coefficient matrices $M'_0, M'_1, \cdots, M'_{t-1}$ sent by the prover may be replaced by a Merkle tree commitment to that matrix, and each query the verifier makes to a matrix is answered by the prover with Merkle tree authentication path for the answer.

And since each time the verifier will query a strip of elements in a matrix (i.e. $M'_i[i_1, i_2, \cdots, i_{t-i-1}, *]$), it's possible to zip such a strip of elements into a single node in Merkle-tree's leaf level to decrease runtime complexity and communication complexity.

2.4.2 Parallelism

Most of the computation in the commitment scheme can be done in parallel in a nature fashion. There's little data dependence among them. Therefore, it's possible to run the commitment scheme using multiple threads to increase efficiency significantly for both the prover and the verifier.

Simple Zero-Knowledge Polynomial Commitments

In this chapter, we describe a simple method to add zero-knowledge property to a given polynomial commitments scheme. This method uses random numbers to hide the actual coefficients and it works similar to one-time pad encryption.

3.1 Protocol

Commitment Phase.

Let $M_0 = u$ and $M_0' = \operatorname{Enc}_1 \circ \operatorname{Enc}_2 \circ \cdots \circ \operatorname{Enc}_{t-1}(M_0) \in \mathbb{F}$ Let PAD_0 be a matrix with shape identical to M_0' filled with random elements from \mathbb{F} . Now let $M_0'' = M_0' \oplus PAD_0$, where \oplus denotes elements-wise matrix addition.

Send M_0'' to the verifier.

Testing Phase.

The testing phase consists of t - 1 rounds, with each round reducing the number of dimensions by 1.

In round i, the verifier will send a random value $r_i \in \mathbb{F}^m$ to the prover. The prover will compute a linear combination $M_i \in \mathbb{F}$ t-i times across the last dimension of matrix M_{i-1} . Namely, for $1 \leq j_1, j_2, \cdots, j_{t-i} \leq m$:

$$M_i[j_1, j_2, \cdots, j_{t-i}] = \sum_{k=1}^m r_i[k] \cdot M_{i-1}[j_1, j_2, \cdots, j_{t-i}, k]$$

Let

$$M_i' = \operatorname{Enc}_1 \circ \operatorname{Enc}_2 \circ \cdots \circ \operatorname{Enc}_{t-i-1}(M_i) \in \mathbb{F} \underbrace{N \times N \times \cdots \times N}_{t-i-1 \text{ times}} \times m$$

$$N \times N \times \cdots \times N$$

The prover will also compute a linear combination $PAD_i \in \mathbb{F}$ t-i timesacross the last dimension of matrix PAD_{i-1} .

Namely, for $1 \le j_1, j_2, \dots, j_{t-i} \le N$:

$$PAD_{i}[j_{1}, j_{2}, \cdots, j_{t-i}] = \sum_{k=1}^{m} r_{i}[k] \cdot PAD_{i-1}[j_{1}, j_{2}, \cdots, j_{t-i}, k]$$

$$N \times N \times \cdots \times N \times m$$

And let $PAD'_i \in \mathbb{F}$ $N \times N \times \cdots \times N \times m$ be a sub-matrix truncated from PAD_i .

Let

$$M_i'' = M_i' \oplus PAD_i'$$

where \oplus denotes element-wise addition.

Then the prover sends M_i'' and PAD_i to the verifier.

Then the verifier will perform a probabilistic checking to make sure M'_0 , M'_1 , M'_{2}, \cdots, M'_{t-1} are consistent with each other. Formally speaking, the verifier will sample l random tuple (i_1, i_2, \dots, i_t) from space $[N] \times [N] \times \dots \times [N]$.

For each tuple (i_1, i_2, \dots, i_t) , the verifier will check whether the following equation holds for every $i \in [t-1]$:

$$\operatorname{Enc}(M_i'[i_1, i_2, \cdots, i_{t-i-1}, *])[i_{t-i}] = \sum_{k=1}^m r_i[k] \cdot M_{i-1}'[i_1, i_2, \cdots, i_{t-i}, k]$$

Since the verifier do not have direct access to M'_0 , M'_1 , M'_2 , \cdots , M'_{t-1} , a detour is necessary. $M'_i[i_1, i_2, \cdots, i_{t-i-1}, *]$ in the left side of the equation can be computed as a element-wise subtraction as follows:

$$M_i''[i_1, i_2, \cdots, i_{t-i-1}, *] - PAD_i'[i_1, i_2, \cdots, i_{t-i-1}, *]$$

And the right side of the equation is equivalent to

$$\left(\sum_{k=1}^{m} r_{i}[k] \cdot M_{i-1}''[i_{1}, i_{2}, \cdots, i_{t-i}, k]\right) - PAD_{i}[i_{1}, i_{2}, \cdots, i_{t-i}]$$

Evaluation Phase.

Let $q_1, q_2, \dots, q_t \in \mathbb{F}^m$ be vectors such that $g(x) = \langle q_1 \otimes q_2 \otimes \dots \otimes q_t, u \rangle$. The evaluation phase is identical to the testing phase, except that in round i, the random value r_i is replaced by q_i . If all consistent checks passed, then the verifier outputs $\langle M'_{t-1}, q_t \rangle$ as g(x), where M_{t-1} can be computed as a element-wise subtraction between M''_{t-1} and PAD'_{t-1} .

3.2 Formal Description

3.2.1 Notation

Fold Operation

Define $\mathbf{Fold}_i(X, r)$ to be the operation taking a linear combination of X across the i-th dimension according to coefficient r.

Namely, for indexes $j_1, \dots, j_{i-1}, j_{i+1}, \dots, j_k \ge 1$:

$$\mathbf{Fold}_{i}(X,r)[j_{1},\cdots,j_{i-1},j_{i+1},\cdots,j_{k}] = \sum_{k=1}^{m} r_{i}[k] \cdot X[j_{1},\cdots,j_{i-1},k,j_{i+1},\cdots,j_{k}]$$

Encode Operation

Define $\operatorname{Enc}_{1,\dots,i}$ be short-hand for $\operatorname{Enc}_{1} \circ \operatorname{Enc}_{2} \circ \dots \circ \operatorname{Enc}_{i}$.

3.2.2 Testing Phase (Proximity Test)

In this section, we describe the testing phase in the above protocol formally in terms of a IOPP (interactive oracle proof of proximity) with point queries for the relation $R_{\otimes}(\mathbb{F}, C, m, N, t)$ between a prover **P** and a verifier **V**.

The prover **P** takes as input an instance $\mathbb{X} = (\mathbb{F}, C, m, N, t)$ and witness $\mathbb{W} = (M_0'', M_1'', \cdots, M_{t-1}'', PAD_1, PAD_2, \cdots, PAD_{t-1})$. The verifier **V** takes as input the instance \mathbb{X} .

1. Interactive phase.

In the beginning, **P** sends the proof message M_0'' computed as:

$$M_0 = u$$

$$M'_0 = \mathbf{Enc}_{1,\dots,t-1}(M_0)$$

$$M''_0 = M'_0 \oplus PAD_0$$

Note that PAD_0 is a matrix with shape identical to M'_0 filled with random elements from \mathbb{F} . And \oplus denotes elements-wise matrix addition.

For each round $i \in [t-1]$:

- **V** sends random challenge message $r_i \in \mathbb{F}^m$.
- P sends the proof message M_i" and PAD_i computed as:

$$PAD_i = \mathbf{Fold}_{t-i+1}(PAD_{i-1}, r_i)$$

 $M_i = \mathbf{Fold}_{t-i+1}(M_{i-1}, r_i)$
 $M'_i = \mathbf{Enc}_{1,\dots,t-i-1}(M_i)$

$$M_i'' = M_i' \oplus PAD_i'$$

Note that PAD'_i is just a truncate version of PAD_i such that M'_i and PAD'_i will have the same shape. And \oplus denotes elementswise addition.

2. *Query phase*. The verifier **V** samples l tuples of the form (i_1, \dots, i_t) in space $[N]^t$ and proceeds as follows for each tuple. For each $i \in [t-1]$, the verifier **V** will query M_i'' , PAD_i'' at $(i_1, \dots, i_{t-i-1}, i_k)$ for each $i_k \in [N]$. And the verifier **V** also needs to query M_0'' at $(i_1, \dots, i_{t-1}, i_k)$ for each $i_k \in [N]$. Then the verifier **V** will check the following equation:

$$\operatorname{Enc}_{t-i}(M'_i)[i_1,\cdots,i_{t-i}] = \operatorname{Fold}_{t-i+1}(M'_{i-1},r_i)[i_1,\cdots,i_{t-i}]$$

Since the verifier **V** do not have direct access to M'_i and M'_{i-1} , we check the following equivalent equation:

$$\operatorname{Enc}_{t-i}(M_i'' \ominus PAD_i')[i_1, \cdots, i_{t-i}] = \operatorname{Fold}_{t-i+1}(M_{i-1}'', r_i)[i_1, \cdots, i_{t-i}] - PAD_i[i_1, \cdots, i_{t-i}]$$
(3.1)

where \ominus denotes element-wise subtraction.

3.2.3 Testing Phase Completeness

Lemma 3.1 IOPP = (P, V) has perfect completeness.

Proof We begin by noting that the queries made by **V** suffice to perform the checks in the query phase (see equation 3.1).

Next, observe that the verifier **V** checks the following equation:

$$\operatorname{Enc}_{t-i}(M_i'' \ominus PAD_i') = \operatorname{Fold}_{t-i+1}(M_{i-1}'', r_i) - PAD_i$$

Note that the left side of this equation is equivalent to:

$$\operatorname{Enc}_{t-i}(M_i'' \ominus PAD_i') = \operatorname{Enc}_{t-i}(M_i')$$

$$= \operatorname{Enc}_{t-i}(\operatorname{Enc}_{1,\dots,t-i-1}(M_i))$$

$$= \operatorname{Enc}_{1,\dots,t-i}(M_i)$$

$$= \operatorname{Enc}_{1,\dots,t-i}(\operatorname{Fold}_{t-i+1}(M_{i-1},r_i))$$
(3.2)
(3.3)

And the right side of this equation is equivalent to:

$$\mathbf{Fold}_{t-i+1}(M''_{i-1}, r_i) - PAD_i = \mathbf{Fold}_{t-i+1}(M'_{i-1}, r_i)$$

$$= \mathbf{Fold}_{t-i+1}(\mathbf{Enc}_{1, \dots, t-i}(M_{i-1}), r_i)$$
(3.4)
$$(3.5)$$

Since both Fold and Enc operations are linear operation, expression 3.2 and expression 3.4 are equivalent to each other. The equation checked by the verifier V holds.

3.2.4 Testing Phase Zero-Knowledge

Definition 3.2 A interactive oracle proof of proximity IOPP = (P, V) for a relation R_{\otimes} is **perfect zero-knowledge** if there exists a polynomial-time simulator algorithm S such that, for every $(X, W) \in R_{\otimes}$ and choice of verifier randomness ρ , the random variables $S^{V(X;\rho)}(X)$ and $View(P(X, W), V(X;\rho))$ are identically distributed.

Lemma 3.3 IOPP = (P, V) is perfect zero-knowledge

Proof For every $(X, W) \in R_{\otimes}$ and choice of verifier randomness ρ , we can construct the polynomial-time simulator algorithm **S** as follows:

• Query M_0'' or internally access PAD_0 at index I:

If index I has never been accessed before, generate a random element x from field \mathbb{F} . Store this value x in a internal dictionary and return it.

Otherwise lookup index I in the internal dictionary and return the stored value.

• Query M_i'' and PAD_i at index I for $i \in [t-1]$:

If index I has never been accessed before, recursively access the corresponding values in M''_{i-1} and PAD_{i-1} and take the linear combination of them as x. Store this value x in a internal dictionary and return it.

Otherwise lookup index I in the internal dictionary and return the stored value.

Both the random variables $\mathbf{S}^{\mathbf{V}(\mathbb{X};\rho)}(\mathbb{X})$ and $\mathrm{View}(\mathbf{P}(\mathbb{X},\mathbb{W}),\mathbf{V}(\mathbb{X};\rho))$ are uniformly distributed. They are identically distributed.

Brakedown Linear Code

4.1 Notation

 α and β are parameters with no explicit meanings. r denotes the ratio between the length of codeword and the length of input message. δ denotes the relevant distance.

4.2 Theoretical Limits for Relevant Distance

In Brakedown paper [1], there're a few explicit constrains for parameter α , β and r. And since binary entropy function used in the linear code is only well-defined between 0 and 1, there's also one more implicit constrain. The full list of constrains are as follows,

$$0 < \alpha < 1$$

$$0 < \beta < \frac{\alpha}{1.28} \tag{4.1}$$

$$r > \frac{1+2\beta}{1-\alpha} > 1 \tag{4.2}$$

$$\delta = \frac{\beta}{r} \tag{4.3}$$

$$\beta + \alpha \beta + 0.03 < r - 1 - r\alpha \tag{4.4}$$

(4.5)

Combine constrain 4.3 and constrain 4.1, we have,

$$\alpha > 1.28 \cdot \delta \cdot r \tag{4.6}$$

Combine constrain 4.3 and constrain 4.2, we have,

$$\alpha > 1 - 2\delta - \frac{1}{r} \tag{4.7}$$

Combine constrain 4.3 and constrain 4.4, we have,

$$\alpha < \frac{r(1-\delta) - 1.03}{r(1+\delta)} \tag{4.8}$$

To make sure α has a valid value, we have,

$$\frac{r(1-\delta) - 1.03}{r(1+\delta)} > 1.28 \cdot \delta \cdot r \tag{4.9}$$

$$\frac{r(1-\delta) - 1.03}{r(1+\delta)} > 1.28 \cdot \delta \cdot r$$

$$\frac{r(1-\delta) - 1.03}{r(1+\delta)} > 1 - 2\delta - \frac{1}{r}$$
(4.9)

(4.11)

Equation 4.9 and equation 4.10 make the maximum possible relevant distance δ to be around 0.12.

Zero-Knowledge Linear Code

5.1 Random d-regular Bipartite Graph

To make sure each vertex has degree d, we can first sample d random perfect matching for 2 sets of n vertices. Then take the union of them. Note that it's possible to generate parallel edges. But this should not be a concern for our purpose here. And it can be shown that this happens with low probability.

Algorithm 1: Random d-regular Bipartite Graph Generation

```
Data: n \ge 0, d <= n

Result: A random d-regular bipartite graph G = (L, R, E) with |L| = |R| = n
L \leftarrow a set of n nodes; R \leftarrow a set of n nodes; E \leftarrow \emptyset; P \leftarrow [1, 2, \cdots, n]; for i in 1, 2, \cdots, d do

Permute P randomly; /* sample a perfect matching */ for j in 1, 2, \cdots, n do

E \leftarrow E \cup (L_j, R_{P_j}); end
end
end
return (L, R, E)
```

5.2 Expander Graph

Lemma 5.1 For any $0 < \epsilon < 1$, there exist a degree d such that a random d-regular bipartite graph G = (L, R, E) with |L| = |R| = n generated according to

algorithm 1 satisfy the following property with high probability.

• Expansion: For every set $X \subset L$ with $|X| \ge \epsilon n$, if Y is the set of neighbors of X in G, then $|Y| \ge (1 - \epsilon)n$.

Proof Negating the statement, we can say that the randomly generated graph G doesn't satisfy the expansion property if and only if $\exists S \subseteq L$, $|S| \ge \epsilon n$, $\exists M \subseteq R$, $|M| \ge \epsilon n$ such that there's no edge connecting between set S and set M. We bound the probability that this negating statement is true as follows:

For every vertex $a \in L$ and every vertex $b \in R$, the probability that a and b are not connected in the random graph G is:

$$P_1 = (\frac{n-1}{n})^d$$

For a set of vertices $S \subset L$ with $|S| = s \ge \epsilon n$, the probability that non of vertices in S is connected to b is:

$$P_2 = (P_1)^s = (\frac{n-1}{n})^{ds}$$

The probability that there exists at least ϵn vertices in R are not connected to any vertex in S is:

$$P_3 = \binom{n}{\epsilon n} (P_2)^{\epsilon n} = \binom{n}{\epsilon n} (\frac{n-1}{n})^{ds\epsilon n}$$

For $0 \le x \le 1$, we denote the binary entropy function to be:

$$H(x) = -x \log_2 x - (1 - x) \log_x (1 - x)$$

where we adopt the convention that $0 \log_2 0 = 0$.

Then, we take a union bound over all possible sets *S*,

$$P_{4} = \sum_{s=\epsilon n}^{n} \binom{n}{s} P_{3}$$

$$= \sum_{s=\epsilon n}^{n} \binom{n}{s} \binom{n}{\epsilon n} (\frac{n-1}{n})^{ds\epsilon n}$$

$$\leq \sum_{s=\epsilon n}^{n} \binom{n}{s} \binom{n}{\epsilon n} (\frac{n-1}{n})^{d\epsilon^{2}n^{2}} \quad \text{since } s \geq \epsilon n \text{ and } \frac{n-1}{n} < 1$$

$$\leq \sum_{s=\epsilon n}^{n} \binom{n}{s} 2^{nH(\frac{\epsilon n}{n})} (\frac{n-1}{n})^{d\epsilon^{2}n^{2}} \quad \binom{n}{k} \leq 2^{nH(\frac{k}{n})}$$

$$= \sum_{s=\epsilon n}^{n} \binom{n}{s} 2^{nH(\epsilon)} ((1-\frac{1}{n})^{n})^{d\epsilon^{2}n}$$

$$\leq \sum_{s=\epsilon n}^{n} \binom{n}{s} 2^{nH(\epsilon)} (\frac{1}{e})^{d\epsilon^{2}n} \qquad (1-\frac{1}{x})^{x} \leq \frac{1}{e} \text{ for } x \geq 1 \text{ (lemma A.2)}$$

$$= \sum_{s=\epsilon n}^{n} \binom{n}{s} (e^{H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$\leq \sum_{s=0}^{n} \binom{n}{s} (e^{H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$= 2^{n} (e^{H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$= (e^{\ln 2 + H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$= (e^{\ln 2 + H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$(5.1)$$

 P_4 is the probability that a randomly generated graph G doesn't satisfy the expansion property. Suppose we want the failing probability be smaller than p, let $(e^{\ln 2 + H(\epsilon) \ln 2 - d\epsilon^2})^n < p$. By rearranging the above equation, we have $d > \frac{\ln 2 + H(\epsilon) \ln 2 - \frac{\ln p}{n}}{\epsilon^2}$.

For example, if $\epsilon=0.05$, n=5000, $p=2^{-256}$, then degree d need to be greater than 370.86.

Lemma 5.2 For any $0 < \epsilon < 1$, there exist a degree d such that a random d-regular bipartite graph G = (L, R, E) with |L| = |R| = n generated according to algorithm 1 satisfy the following property.

• Expansion: For every set $X \subset L$ with $|X| \ge \epsilon n$, if Y is the set of neighbors of X in G, then $|Y| \ge (1 - \epsilon)n$ with high probability.

Proof We use the same trick as in lemma 5.1. Negating the statement, we can say that the randomly generated graph *G* doesn't satisfy the expansion

property if and only if for every $S \subseteq L$, $|S| \ge \epsilon n$, $\exists M \subseteq R$, $|M| > \epsilon n$ such that there's no edge connecting between set S and set M with low probability. We bound the probability true as follows:

For every vertex $a \in L$ and every vertex $b \in R$, the probability that a and b are not connected in the random graph G is:

$$P_1 = (\frac{n-1}{n})^d$$

For a set of vertices $S \subset L$ with $|S| = \epsilon n$, the probability that non of vertices in S is connected to b is:

$$P_2 = (P_1)^{\epsilon n} = (\frac{n-1}{n})^{d\epsilon n}$$

The probability that there exists at least ϵn vertices in R are not connected to any vertex in S is:

$$P_{3} = \binom{n}{\epsilon n} (P_{2})^{\epsilon n}$$

$$= \binom{n}{\epsilon n} (\frac{n-1}{n})^{d\epsilon^{2}n^{2}}$$

$$\leq 2^{nH(\frac{\epsilon n}{n})} (\frac{n-1}{n})^{d\epsilon^{2}n^{2}} \qquad \binom{n}{k} \leq 2^{nH(\frac{k}{n})}$$

$$= 2^{nH(\epsilon)} ((1-\frac{1}{n})^{n})^{d\epsilon^{2}n}$$

$$\leq 2^{nH(\epsilon)} (\frac{1}{e})^{d\epsilon^{2}n} \qquad (1-\frac{1}{x})^{x} \leq \frac{1}{e} \text{ for } x \geq 1 \text{ (lemma A.2)}$$

$$= (e^{H(\epsilon) \ln 2 - d\epsilon^{2}})^{n}$$

$$(5.2)$$

 P_3 is the probability that a set S in a randomly generated graph doesn't satisfy the expansion property. Suppose we want the failing probability be smaller than p, let $(e^{H(\epsilon)\ln 2 - d\epsilon^2})^n < p$. By rearranging the above equation, we have $d > \frac{H(\epsilon)\ln 2 - \ln p}{\epsilon^2}$.

For example, if $\epsilon=0.05$, n=5000, $p=2^{-256}$, then degree d need to be greater than 93.60.

Compared with lemma 5.1, lemma 5.2 produces a much tighter bound by weakening the expansion property. A graph satisfy the expansion property

in lemma 5.2 may not satisfy the expansion property in lemma 5.1. There may exist a set $S \subset L$ in graph such that the expansion property fails. But lemma 5.2 guarantees that such set is hard to be found. Similar with hash functions, hash collision must exist somewhere, but this collision is hard to be found.

5.3 Reversed Linear Code

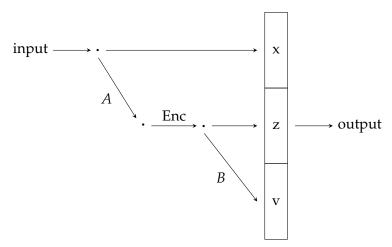

Figure 5.1: Linear Code

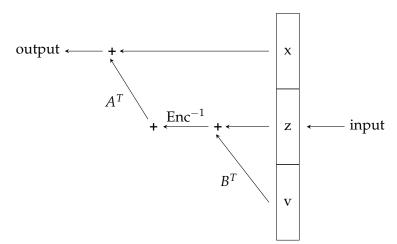

Figure 5.2: Reversed Linear Code

Appendix A

Math Preliminary

Lemma A.1 $\binom{n}{m} \leq (\frac{en}{m})^m$, for $n, m \in \mathbb{Z}^+$

Proof

$$\log m! = \log 1 + \log 2 + \dots + \log m$$

$$\geq \int_{1}^{m} \log x \, dx$$

$$= [x \log x - x]_{1}^{m}$$

$$= m \log m - m + 1 \tag{A.1}$$

$$m! = e^{\ln m!}$$

$$\geq e^{m \log m - m + 1} \qquad \text{apply equation A.1}$$

$$= e^{\log m^m} \cdot e^{-m} \cdot e$$

$$= m^m \cdot e^{-m} \cdot e$$

$$= (\frac{m}{e})^m \cdot e$$

$$\geq (\frac{m}{e})^m \qquad (A.2)$$

$$\binom{n}{m} = \frac{n \cdot (n-1) \cdot (n-2) \cdots (n-m+1)}{m!}$$

$$\leq \frac{n^m}{m!}$$

$$\leq \frac{n^m}{(\frac{m}{e})^m} \qquad \text{apply equation A.2}$$

$$= (\frac{en}{m})^m \qquad (A.3)$$

Lemma A.2 $(1 - \frac{1}{x})^x \le \frac{1}{e}$, for $x \ge 1$

Proof

Recall that for $x \in \mathbb{R}$

$$1 + x < e^x$$

Then for $x \in \mathbb{R}$

$$1 - x < e^{-x}$$

Then for $x \neq 0$

$$1 - \frac{1}{r} \le e^{-\frac{1}{x}}$$

And, since $t \mapsto t^x$ is increasing on $[0, \infty]$ for $x \ge 1$

$$(1 - \frac{1}{x})^x \le \frac{1}{e} \tag{A.4}$$

Lemma A.3 $\left(\frac{a}{r}\right)^x \le e^{\frac{a}{e}}$, for x > 0, a > 0

Proof

Let $f(x) = (\frac{a}{x})^x$

$$\ln f(x) = x \cdot \ln(\frac{a}{x}) = -x \cdot \ln \frac{x}{a}$$

Take derivative from both side
$$\frac{1}{f(x)}\frac{df(x)}{dx} = -\ln\frac{x}{a} - x \cdot \frac{a}{x} \cdot \frac{1}{a} = -\ln\frac{x}{a} - 1$$

$$\frac{df(x)}{dx} = -f(x) \cdot (\ln\frac{x}{a} + 1) = -(\frac{a}{x})^x \cdot (\ln\frac{x}{a} + 1)$$

Let $\frac{df(x)}{dx} = 0$

$$-\left(\frac{a}{x}\right)^{x} \cdot \left(\ln \frac{x}{a} + 1\right) = 0$$
$$\left(\ln \frac{x}{a} + 1\right) = 0$$

$$x = \frac{a}{e}$$

 $\frac{df(x)}{dx} > 0$ when $x < \frac{a}{e}$, and $\frac{df(x)}{dx} < 0$ when $x > \frac{a}{e}$

Therefore, $x = \frac{a}{e}$ is a maximum point

$$\left(\frac{a}{x}\right)^{x} = f(x) \le f\left(\frac{a}{e}\right) = e^{\frac{a}{e}} \tag{A.5}$$
